Coalition Description Logic with Individuals

Abstract
Coalitional Description Logic [17] is a product style combination of Coalition Logic and the description logic $\mathcal{ALC}$. It enables reasoning about agents' ability to influence first-order structures. In this paper, we extend the logic with nominals, i.e., names of individuals including those of agents to define more complex terms for coalitions. This extended language allows one to express surprisingly sophisticated properties because it provides a way to reason about how agents can influence themselves. After introducing the new logic formally, we show that its satisfiability problem is still decidable in $\text{NEXPTIME}$. We prove it constructively by proposing a tableau.

Keywords: strategic logic, description logic, multi-agent systems, tableau

1 Introduction
Coalition logic (CL) [14,15] formalizes the ability of groups of agents to achieve certain outcomes in strategic games. The central operator of the logic is $[A]$, with $[A] \varphi$ meaning that group of agents $A$ has a strategy to achieve an outcome state where $\varphi$ holds. On the other hand, description logics (DLs) are logical formalisms for representing the knowledge of an application domain in a structured way [2]. More precisely, DLs allow to describe classes, assign individuals to these classes, and define binary relations on individuals. The importance of DLs lies in the fact that they are decidable fragments of first-order logic and they have well developed practical decision procedures. Moreover, they comprise the formal basis of the Semantic Web ontology languages [10].

In [17], we proposed a product style combination of the description logic $\mathcal{ALC}$ with coalition logic, that allowed for application of modal operators to both formulas and concepts. Still, the combination kept the agent and the concept layers pretty

much separated; in particular, one could not use the first-order elements of DL to specify how agents and their groups can influence themselves. In this paper, we make the first step to overcome the drawback: we extend the language of concepts with names of individuals (including agents), and we allow for more complex terms to define coalitions. This simple extension allows to express surprisingly sophisticated properties, as the examples in Section 2.4 demonstrate. Furthermore, we extend the satisfiability procedure from [17] to handle the new language, and we establish complexity bounds for the satisfiability problem.

It is worth noting that we do not presuppose any general relationship between agents’ first-order properties and their temporal abilities in our logic. In particular, if a formula is satisfiable (resp. valid) then one can replace any occurrence of an agent name in the formula with any other agent name, and the resulting formula will be still satisfiable (resp. valid). Note that this symmetry of agents’ abilities with respect to the actual actor is a general feature of CL, and not specifically of our combination of CL and description logic. On the other hand, agents used in coalitions and agents used as individuals are semantically related: given a particular model (or a particular theory), we cannot shuffle agent names without changing the truth values of formulae anymore.

2 The Logic

In this section we define our logic formally. We begin by disentangling the syntax and semantics of coalitional expressions: in all the existing literature on strategic logics, no difference is made between sets of “real” agents and the descriptions that refer to them (cf. [15,1] and many others). Instead, it is assumed that the agents themselves occur in formulae of the logics. Such an abuse of formal notation seems acceptable when we refer to agents only in the scope of strategic operators (to name who is supposed to achieve the property in question). In our case, however, we want also to reason about agents (resp. coalitions) in the same way as about other individuals (resp. concepts). That is, we want to enjoy the benefits of first-order reasoning with respect to agents and their sets, and make sure that we do it correctly.

After defining the syntax of coalitional expressions (and formulas in which those can occur), we extend our semantics from [17] to handle the new, more sophisticated concepts and agent expressions. Finally, we present some intuitive examples, and show that every formula of CL,ACC holds can be equivalently transformed to a more rigid form, which will prove convenient when defining our decision procedure in further sections.

2.1 Syntax

In order to specify properties of agents and coalitions, we assume the following sets of names: a countable set \( N_C \) of concept names that includes at least \( \text{Agt} \) (the name for the “grand coalition” of agents), a countable set \( N_R \) of role names, a finite nonempty set \( N_I \) of individual names, and a finite nonempty set \( N_A \subseteq N_I \) of agent names. The set of concepts is the smallest set satisfying the following conditions:
\begin{itemize}
  \item $\top$ is a concept (top concept), and every concept name is a concept;
  \item If $i_1, \ldots, i_n$, $n \geq 0$, are individual names then $\langle i_1, \ldots, i_n \rangle$ is a concept (enumeration of individuals);
  \item If $C$ is a concept and $R$ is a role name then $\forall R.C$ and $\exists R.C$ are concepts;
  \item If $C$ and $D$ are concepts then $C \cap D$, $C \cup D$, and $C \setminus D$ are also concepts;
  \item If $C$ is a concept and $A$ is a coalitional term (defined further) then $[A]C$ and $\langle A \rangle C$ are concepts.
\end{itemize}

A \textit{coalitional term} is a concept that includes only names from $N_A \cup \{\text{Agt}\}$. Therefore, coalitional terms contain no concept names (except $\text{Agt}$), no role names, and no ‘non-agent’ individual names.

Additionally, we define $\bot \equiv \emptyset$ (bottom concept), and $\neg C \equiv \top \setminus C$. Concept names, $\top$, and concepts of type $\langle i_1, \ldots, i_n \rangle$ form the set of \textit{atomic concepts}. Also, for any individual names $i_1, \ldots, i_n \in N_I$, we will use the following notation: $\text{enumterm}(\langle i_1, \ldots, i_n \rangle) = \langle i_1, \ldots, i_n \rangle$, and conversely, $\text{enumset}(\langle i_1, \ldots, i_n \rangle) = \{i_1, \ldots, i_n\}$. When we give the semantics it will be clear that no matter how we choose to enumerate a given set of individual names by $\text{enumterm}(\cdot)$, they will yield equivalent interpretations.

Now we can define the set formulas of $\text{CL}_{\text{ALCO}}$ as follows: if $C, D$ are concepts then $C \subseteq D$ and $C = D$ are (atomic) formulas; if $\varphi, \psi$ are formulas then $\neg \varphi, \varphi \land \psi, \varphi \lor \psi$ are formulas; if $\varphi$ is a formula and $A$ is a coalitional term then $[A] \varphi, \langle A \rangle \varphi$ are also formulas.\footnote{We will sometimes use $[i_1, \ldots, i_n]$ (resp. $\langle i_1, \ldots, i_n \rangle$) as a shorthand for $\langle \{i_1, \ldots, i_n\}\rangle$ (resp. $\langle \{i_1, \ldots, i_n\}\rangle$), both in strategic operators and concept constructors.}

Thus, $\text{CL}_{\text{ALCO}}$ extends the description logic $\text{ALCO}$ with modal operators $[A], \langle A \rangle$ for reasoning about how agents can transform the world, but also with means to single out agents from concepts (agent names, special concept $\text{Agt}$), and with concepts $[A]C, \langle A \rangle C$ that group objects depending on how they can be transformed. On the other hand, $\text{CL}_{\text{ALCO}}$ extends coalition logic with elements of dyadic first-order logic, typical for description logics.

\subsection{Models}

A \textit{model} for $\text{CL}_{\text{ALCO}}$ is a quadruple of the form $\mathfrak{M} = (\text{Agt}, W, E, I)$, where $\text{Agt}$ is a finite nonempty set of agents, $W$ is a nonempty set of possible worlds (states), and $E, I$ associate a \textit{playable effectivity function} $E_w$ and an $\text{ALCO}$-interpretation $I(w)$ with every world $w \in W$.

An effectivity function is defined as $E_w : 2^\text{Agt} \to 2^W$, i.e., a function that assigns a set of achievable outcomes $V \subseteq W$ to each coalition $A \subseteq \text{Agt}$. The complement sets for outcomes and coalitions are defined as $\overline{V} = W \setminus V$ and $\overline{A} = \text{Agt} \setminus A$, respectively. $E_w$ is \textit{playable} iff it satisfies the following conditions:

(i) \textit{Semi-seriality}: $\emptyset \not\in E_w(A)$, for all coalitions $A \neq \text{Agt}$;
(ii) \textit{Semi-W-completeness}: $W \in E_w(A)$, for all coalitions $A \neq \text{Agt}$;
(iii) \textit{Semi-outcome-monotonicity}: for all $V \subseteq U \subseteq W$ and for all $A \neq \text{Agt}$, if $V \in E_w(A)$ then $U \in E_w(A)$;
(iv) \textit{Semi-superadditivity}: for all $V, U, A_1, A_2$ such that $A_1 \cap A_2 = \emptyset$ and
A_1 \cup A_2 \neq \text{Agt}, if V \in E_w(A_1) and U \in E_w(A_2) then V \cap U \in E_w(A_1 \cup A_2); (v) \text{Agt-maximality: for all } V, \text{ if } \overline{V} \notin E_w(\emptyset) \text{ then } V \in E_w(\text{Agt}); (vi) \text{Regularity: for all } V, A, \text{ if } V \in E_w(A) \text{ then } \overline{V} \notin E_w(A).

Additionally, we call an effectivity function \textit{semi-playable} iff it satisfies conditions (i)-(iv). Although the standard definition of playability does not make any exceptions for the grand coalition, we do not lose anything by the above definition of playability because semi-playability together with \text{Agt-maximality and regularity is equivalent to (standard) playability [15].}

An \text{AŁCO}-interpretation \( \mathcal{I}(w) = (\Delta^I(w), \mathcal{I}(w)) \), includes a nonempty set \( \Delta^I(w) \) called the \textit{domain} of state \( w \), and a mapping \( \mathcal{I}(w) \) that assigns each concept name \( C \) with a subset \( C^{I}(w) \) of \( \Delta^I(w) \), each role name \( R \) with a binary relation \( R^{I}(w) \) on \( \Delta^I(w) \), and each individual name \( i \) with an element \( i^{I}(w) \) in \( \Delta^I(w) \). We make the following semantic assumptions wrt \text{AŁCO}-interpretations:

- \textit{Constant domain: } \( \Delta^I(w) = \Delta^I(v) \) for any \( w, v \in W \);
- \textit{Global individual names: } \( i^{I}(w) = i^{I}(v) \) for all \( i \in N_I \) and \( w, v \in W \);
- \textit{Unique individual names: } \( i_1^{I}(w) \neq i_2^{I}(w) \) for two distinct individual names \( i_1, i_2 \in N_I \) and all \( w \in W \);
- \textit{Correct interpretation of agent names: } \( \text{Agt}^{I}(w) = \text{Agt} \) and \( \{ i \mid i = a^{I}(w) \text{ for some } a \in N_A \} = \text{Agt} \) for every \( w \in W \).

As a consequence of our assumptions, agents are a part of domain in every state, and can be referred to like all other concepts and individuals. Moreover, the interpretation of coalitional terms does not change from state to state, and the cardinality of the set of agents \( \text{Agt} \) must be the same as the number of agent names given in \( N_A \). Note that we have chosen to make the unique individual names assumption because otherwise two different agent names inside modal operators might denote the same agent, leading to a peculiar effect.

In short, models of \text{CL_{AŁCO}} combine information about possible states of reality \((W)\), and how they can be transformed \((E)\), and by whom \((\text{Agt})\), with first-order structures that characterize each possible world separately.

2.3 Semantics

The interpretation \( \mathcal{I}(w) \) defines the denotation of individual names and primitive concepts in state \( w \). We extend it to concept descriptions in a similar way to [17]:

\[
\begin{align*}
\top^{I}(w) & = \Delta^I(w), \\
\{i_1, \ldots, i_n\}^{I}(w) & = \{i_1^{I}(w), \ldots, i_n^{I}(w)\}, \\
(C \cap D)^{I}(w) & = C^{I}(w) \cap D^{I}(w), \\
(C \cup D)^{I}(w) & = C^{I}(w) \cup D^{I}(w), \\
(C \setminus D)^{I}(w) & = C^{I}(w) \setminus D^{I}(w), \\
(\forall R.C)^{I}(w) & = \{ \delta \in \Delta^I(w) \mid \forall \delta' (\langle \delta, \delta' \rangle \in R^{I}(w) \rightarrow \delta' \in C^{I}(w)) \}, \\
(\exists R.C)^{I}(w) & = \{ \delta \in \Delta^I(w) \mid \exists \delta' (\langle \delta, \delta' \rangle \in R^{I}(w) \land \delta' \in C^{I}(w)) \}, \\
(\lnot C)^{I}(w) & = \{ \delta \in \Delta^I(w) \mid \|C\|^{\overline{w}}_\delta \notin E_w(\delta^{I}(w)) \}, \\
(\langle A \rangle C)^{I}(w) & = \{ \delta \in \Delta^I(w) \mid W \setminus \|C\|^{\overline{w}}_\delta \notin E_w(\delta^{I}(w)) \},
\end{align*}
\]
where \(|C|_\delta^n = \{ w \in W \mid \delta \in C^{I(w)} \}\) is the set of states that \(\delta\) belongs to the interpretation of concept \(C\).

Now we define the satisfaction relation \(\models\) for \(\text{CL}_{\text{ALCO}}\) as follows:

\[
\begin{align*}
\mathcal{M}, w \models C \subseteq D & \iff C^{I(w)} \subseteq D^{I(w)}, \\
\mathcal{M}, w \models C = D & \iff C^{I(w)} = D^{I(w)}, \\
\mathcal{M}, w \models \neg \varphi & \iff \mathcal{M}, w \not\models \varphi, \\
\mathcal{M}, w \models \varphi \land \psi & \iff \mathcal{M}, w \models \varphi \text{ and } \mathcal{M}, w \models \psi, \\
\mathcal{M}, w \models \varphi \lor \psi & \iff \mathcal{M}, w \models \varphi \text{ or } \mathcal{M}, w \models \psi, \\
\mathcal{M}, w \models [A] \varphi & \iff \|\varphi\|^M \in E_w(A^{I(w)}), \\
\mathcal{M}, w \models <A> \varphi & \iff W \setminus \|\varphi\|^M \notin E_w(A^{I(w)}),
\end{align*}
\]

where \(|\varphi|^M = \{ w \in W \mid \mathcal{M}, w \models \varphi \}\) is the set of states that satisfy \(\varphi\) in \(\mathcal{M}\). We observe that the possibility/necessity of \(\varphi\) being true in the next moment can be expressed with operators \([\text{Agt}], [ ] \): \([\text{Agt}] \varphi\) can be read as “there is a possible next state for which \(\varphi\) holds”, while \([ ] \varphi\) expresses that in every possible next state \(\varphi\) is the case.

A formula \(\varphi\) is satisfiable if there exist a model \(\mathcal{M} = \langle W, E, I \rangle\) and a state \(w \in W\) such that \(\mathcal{M}, w \models \varphi\). A concept \(C\) is satisfiable if there exist \(\mathcal{M} = \langle W, E, I \rangle\) and \(w \in W\) such that \(C^{I(w)} \neq \emptyset\). Concept \(D\) subsumes concept \(C\) if \(C^{I(w)} \subseteq D^{I(w)}\) for all models \(\mathcal{M} = \langle W, E, I \rangle\) and all \(w \in W\). Note that concept subsumption and concept satisfiability can be reduced to formula (un)satisfiability. Concept \(C\) is satisfiable iff formula \(\neg(C \subseteq \bot)\) is satisfiable and concept \(D\) subsumes concept \(C\) iff formula \(\neg(C \subseteq D)\) is unsatisfiable. The formula \(C \subseteq D\) is clearly equivalent to \(\top \subseteq \neg C \cup D\), and \(C = D\) to \(\top \subseteq (\neg C \cup D) \cap (\neg D \cup C)\). In the remainder of this paper, we will assume without loss of generality that every atomic formula is of the form \(\top \subseteq E\) and we will restrict our attention to satisfiability of formulas.

### 2.4 Examples, Properties, Remarks

In the examples, we will use \(a_1, a_2, \ldots\) for agents’ names, and \(a_1, a_2, \ldots\) for the agents that these names refer to.

**Example 2.1** Formula \([a]\{a\} \subseteq \text{Happy}\) specifies that agent \(a\) can make himself happy. We can write similar specifications for coalitions: \([a_1, a_2]\{\{a_1, a_2\}\} \subseteq \text{Happy}\) says that \(a_1\) and \(a_2\) can make themselves happy if they cooperate. Furthermore, \([a_1, a_2]\{\text{Agt} \subseteq \text{Happy}\}\) states that \(a_1, a_2\) can make all the agents happy.

Consider formula \((\text{Agt} \cap [a] \text{Happy}) \subseteq \text{Happy}\). Clearly, it says that \(a\) cannot make anybody happier than now. Moreover, \(\langle \text{Agt} \setminus [a] \rangle\{\langle \text{Agt} \cap [a] \text{Happy} \rangle \subseteq \text{Happy}\}\) adds that all the other agents can do nothing to change this sad state of affairs.

**Example 2.2** Let \(\text{Perm}\) stand for the set of permissions to be in a building, and \(\text{In}\) represent the set of agents that are currently inside. Formula \(!\bigwedge_{a \in N_A} (\text{admin} \{a\} \subseteq \text{Perm}) \land \text{admin} \neg(\{a\} \subseteq \text{Perm})\) specifies that the administrator can grant and
deny the permission to any agent. Moreover, \( \wedge_{a \in N_A} \neg (\{a\} \subseteq \text{In}) \rightarrow (\{a\} \subseteq \text{Perm} \leftrightarrow [a](\{a\} \subseteq \text{In})) \) says that an agent is able to enter the building if, and only if, he has a permission to do so.

Note that the specifications refer only to the agents’ abilities in the current moment, while it would be rather more appropriate to specify them as invariants of the scenario. This is one of the drawbacks of coalition logic, and a reason why extending our logic with ATL operators [1] seems an interesting avenue for future research.

\[\text{Example 2.3} \text{ Consider a system with a dynamic hierarchy of processes captured by the role name, and a dynamic configuration of active processes represented by the concept Active. Formula } \wedge_{a \in N_A} (\text{Active} \cap [a] \text{Active}) = \exists \text{parent}. \{a\} \text{ says that agents can deactivate exactly those processes they are parents of. Adding a requirement that an agent cannot activate a process without becoming its parent: } \wedge_{a \in N_A} \neg \text{Active} \cap [a] (\text{Active} \cap \exists \text{parent}. \{a\}) = \bot \text{ makes for a viable specification of a hierarchic multi-process system.} \]

In the next sections we will present a procedure that constructs models for such specifications (provided they are satisfiable). Before we go on to presenting our satisfiability algorithm, however, we show that the input formula of the procedure can be given in a slightly simplified form without any loss of generality.

\[\text{Lemma 2.4} \text{ Let } A, B \text{ be coalitional terms. Every coalitional term in the form } [A]B \text{ is equivalent to } B, \text{ i.e., } ([A]B)^{I(w)} = B^{I(w)} \text{ for every model } M \text{ and state } w. \text{ The same holds for } \langle A \rangle B. \]

\[\text{Proof.} ([A]B)^{I(w)} = \{ \delta \in \Delta^{I(w)} \mid ||B||^0_\delta \in E_w(A^{I(w)}) \} \text{ where } ||B||^0_\delta = \{ w' \in W \mid \delta \in B^{I(w')} \}. \text{ Since the interpretation of coalitional terms does not change from state to state, we get that } ||B||^0_\delta = W \text{ if } \delta \in B^{I(w)} \text{ and } \emptyset \text{ otherwise. By playability of } E_w, \text{ we have } W \in E_w \text{ and } \emptyset \notin E_w, \text{ so } ([A]B)^{I(w)} = \{ \delta \in \Delta^{I(w)} \mid \delta \in B^{I(w)} \} = B^{I(w)}. \text{ The proof for } \langle A \rangle B \text{ is analogous.} \]

A formula is singleton reduced iff every enumeration of individuals not appearing inside a modal operator is of the form \( \{i\} \); difference free iff it does not contain \( \setminus \); in negation normal form (NNF) iff negation signs appear only in front of atomic formulas, concept names, and enumeration of individuals; and coalitionally simple iff all the coalitional terms it includes are of the form \( \{a_1, \ldots, a_k\} \), with \( a_1, \ldots, a_k \in N_A \).

A formula can be transformed to an equivalent singleton reduced formula by the concept equivalences \( \{i_1, \ldots, i_n\} \equiv \{i_1\} \cup \ldots \cup \{i_n\} \) [2] and \( \{\} \equiv \bot \); to a difference free formula by the equivalence \( C \setminus D \equiv C \cap \neg D \); and to a formula in NNF by making use of de Morgan’s laws, the duality between value restrictions and full existential quantifications, and the duality between modal operators. We denote the NNF of formula \( \varphi \) (resp. concept \( C \)) by \( \neg \neg \varphi \) (resp. \( \neg \neg C \)). For coalitionally simple formulas, we use the following proposition.

\[\text{Proposition 2.5} \text{ For every formula } \varphi \text{ there is an equivalent coalitionally simple formula } \varphi', \text{ i.e., such that } M,w \models \varphi \text{ iff } M,w \models \varphi' \text{ for every } M,w. \text{ Moreover, } \varphi' \text{ is at most linearly longer than } \varphi, \text{ and can be obtained in linear time wrt the length of} \]
Proof. We use the following translation scheme:

- \( tr_1 \) replaces every occurrence of \( \text{Agt} \) in \( \varphi \) with \( \text{enumterm}(N_A) \);
- \( tr_2 \) replaces every occurrence of \( [A]B \) and \( \langle A \rangle B \) with \( B \) (recursively, proceeding from atomic concepts and subformulas to more complex ones);
- \( tr_3 \) replaces (recursively) every occurrence of \( \{a_1, \ldots , a_n\} \cap \{a_1', \ldots , a_n'\} \) (where \( a_i, a_i' \in N_A \) with \( \text{enumterm}(\{a_1, \ldots , a_n\} \cap \{a_1', \ldots , a_n'\}) \), and analogously for \( \cup, \cap \).

Then, \( \varphi' = tr_3(tr_2(tr_1(\varphi))) \) is coatomically simple and equivalent to \( \varphi \) (the proof is straightforward).

In fact, we will mainly consider coatomically simple, singleton reduced, and difference free formulas in negation normal form.

Remark 2.6 We have chosen to interpret the set \( N_A \) as including the names of existing rather than potential agents. It may seem somewhat restrictive when writing specifications: after we have decided on a precise syntax (including the set of agent names \( N_A \)), the number of agents is completely fixed in the models of our logic. Alternatively, we could assume a countable set of available agent names, and provide denotations for only a finite subset of those in each particular model. We are planning to explore the possibility in the future.

3 Hintikka Structures for \( \text{CL}_{\text{ALCO}} \)

Decision procedures based on semantic tableaux construct not a model of the given formula, but a structure closely resembling a model, called a Hintikka structure [16]. A Hintikka structure makes use of Hintikka sets [9] which are also called downward saturated sets in the literature. Some authors prefer using alternative names such as model graph [7] or tableau [11] for referring to the same abstraction of a model.

In this section, we specify Hintikka structures for \( \text{CL}_{\text{ALCO}} \)-formulas. The proofs showing their equivalence to \( \text{CL}_{\text{ALCO}} \) models are omitted for reasons of space but they combine results of [17,11].

For a \( \text{CL}_{\text{ALCO}} \)-formula \( \varphi \), denote by

- \( \text{con}(\varphi) \) the set of all \( \text{CL}_{\text{ALCO}} \)-concepts occurring in \( \varphi \),
- \( \text{rol}(\varphi) \) the set of all role names occurring in \( \varphi \),
- \( \text{for}(\varphi) \) the set of all subformulas of \( \varphi \),
- \( \text{con}^{-}(\varphi) = \text{con}(\varphi) \cup \{ \neg C \mid C \in \text{con}(\varphi) \} \),
- \( \text{fcl}(\varphi) = \text{for}(\varphi) \cup \{ [\theta] \mid \langle \text{enumterm}(N_A) \rangle \theta \in \text{for}(\varphi) \} \),
- \( \text{ccl}(\varphi) = \text{con}^{-}(\varphi) \cup \{ [\theta] \mid \langle \text{enumterm}(N_A) \rangle \theta \in \text{con}^{-}(\varphi) \} \cup \{ \{ i \} \mid i \in N_I \} \).

Definition 3.1 If \( \varphi \) is a \( \text{CL}_{\text{ALCO}} \) formula, a basic Hintikka structure for \( \varphi \) is defined to be a hextuple \( H = (\Sigma, \Lambda, S, \mathcal{L}, \mathcal{E}, \mathcal{F}) \) such that

- \( \Sigma \) is a nonempty set of states,
- \( \Lambda : \Sigma \rightarrow 2^{\text{fcl}(\varphi)} \) maps each state to a set of formulas which is a subset of \( \text{fcl}(\varphi) \),
- \( S \) is a map associating with each \( w \in \Sigma \) a nonempty set of concept types,
• $\mathcal{L}$ associates with each state $w \in \Sigma$ a function
  
  \[ \mathcal{L}_w : \mathcal{S}(w) \to 2^{\text{ccl}(\varphi)} \]

  that maps each concept type $s$ in $\mathcal{S}(w)$ to a set of concepts which is a subset of $\text{ccl}(\varphi)$,

• $\mathcal{E}$ associates with each state $w \in \Sigma$ a function
  
  \[ \mathcal{E}_w : \text{rol}(\varphi) \to 2^{\mathcal{S}(w) \times \mathcal{S}(w)} \]

  that maps each role $R$ in $\text{rol}(\varphi)$ to a set of pairs of concept types from $\mathcal{S}(w)$,

• $\mathcal{J}$ associates with each state $w \in \Sigma$ a function
  
  \[ \mathcal{J}_w : N_I \to \mathcal{S}(w) \]

  that maps individual names to concept types in $\mathcal{S}(w)$ such that $i \neq j$ implies $\mathcal{J}_w(i) \neq \mathcal{J}_w(j)$, and $\mathcal{J}_w(i) = \mathcal{J}_w(j)$ for all $v \in \Sigma$,

• there is some $w_\varphi \in \Sigma$ such that $\varphi \in \Lambda(w_\varphi)$.

Furthermore, for all $w \in \Sigma$, $s,t \in \mathcal{S}(w)$, $\vartheta, \vartheta_1, \vartheta_2 \in \text{fcl}(\varphi)$, $C,C_1,C_2 \in \text{ccl}(\varphi)$, $R \in \text{rol}(\varphi)$, $i \in N_I$, it holds that:

(P$_\bot$) $\bot \notin \mathcal{L}_w(s)$;

(P$_\cap$) if $C \in \mathcal{L}_w(s)$ then $\neg C \notin \mathcal{L}_w(s)$, where $C$ is a concept name or of the form $\{i\}$;

(P$_w$) if $C_1 \cap C_2 \in \mathcal{L}_w(s)$ then $C_1 \in \mathcal{L}_w(s)$ and $C_2 \in \mathcal{L}_w(s)$;

(P$_1$) if $C_1 \cup C_2 \in \mathcal{L}_w(s)$ then $C_1 \in \mathcal{L}_w(s)$ or $C_2 \in \mathcal{L}_w(s)$;

(P$_\forall$) if $\forall R.C \in \mathcal{L}_w(s)$ and $(s,t) \in \mathcal{E}_w(R)$ then $C \in \mathcal{L}_w(t)$;

(P$_\exists$) if $\exists R.C \in \mathcal{L}_w(s)$ then there is some $s' \in \mathcal{S}$ such that $\langle s,s' \rangle \in \mathcal{E}_w(R)$ and $C \in \mathcal{L}_w(s')$;

(P$_\exists$) $\{i\} \in \mathcal{L}_w(s)$ iff $s = \mathcal{J}(i)$;

(P$_\bigcup$) if $\top \subseteq C \in \Lambda(w)$ then $C \in \mathcal{L}_w(s)$;

(P$_\exists$) $\neg(\top \subseteq C) \in \Lambda(w)$ then there is some $s' \in \mathcal{S}$ such that $\neg C \in \mathcal{L}_w(s')$;

(P$_\land$) if $\vartheta_1 \land \vartheta_2 \in \Lambda(w)$ then $\vartheta_1 \in \Lambda(w)$ and $\vartheta_2 \in \Lambda(w)$;

(P$_\lor$) if $\vartheta_1 \lor \vartheta_2 \in \Lambda(w)$ then $\vartheta_1 \in \Lambda(w)$ or $\vartheta_2 \in \Lambda(w)$;

(P$_\land^\text{term}$) if $\langle \text{enumterm}(N_A) \rangle C \in \mathcal{L}_w(s)$ then $[\vartheta]C \in \mathcal{L}_w(s)$, and if $\langle \text{enumterm}(N_A) \rangle \vartheta \in \Lambda(w)$ then $[\vartheta] \vartheta \in \Lambda(w)$.

Modal operators, regardless of being in front of formulas or concepts, impose additional properties on basic Hintikka structures. To define these properties in a more uniform way, we will use a notational convenience.

**Definition 3.2** Let $\langle \Sigma, \Lambda, \mathcal{S}, \mathcal{L}, \mathcal{E}, \mathcal{J} \rangle$ be a basic Hintikka structure for $\varphi$. For a state $w \in \Sigma$, the set $\Phi_w$ is defined as

\[ \Phi_w := \Lambda(w) \cup \{s : C \mid C \in \mathcal{L}_w(s) \text{ and } s \in \mathcal{S}\}. \]

$\alpha$ and $\beta$ are placeholders for elements of $\Phi_w$. $\triangledown \alpha$ is either equal to some $\triangledown \vartheta$ or $s : \triangledown C$, where $\triangledown \in \{\langle A \rangle, \langle \Lambda \rangle\}$ for some coalescional term $A$. If $\triangledown \alpha = \triangledown \vartheta$ then $\alpha = \vartheta$; and if $\triangledown \alpha = s : \triangledown C$ then $\alpha = s : C$.

As the reader familiar with tableau would notice, the meanings of symbols $\alpha$ and $\beta$ in our uniform notation are different than in Smullyan’s notation to classify formulas [4]. We are interested in certain set of modal expressions called modal saturations.
Definition 3.3 \( \Psi \subseteq \Phi_w \) is called a modal saturation in a state \( w \in \Sigma \) of a basic Hintikka structure if and only if \( \Psi \) is equal to

\[
(S_{[A_i]} \{ [A_1] \alpha_1, \ldots, [A_n] \alpha_n \} \text{ such that } a \in \text{enumset}(A_i) \cap \text{enumset}(A_j) \) implies \( i = j \),
\]

\[
(S_{[A_i]} \{ [A_1] \alpha, [A_1] \alpha_1, \ldots, [A_n] \alpha_n \} \text{ such that } a \in \text{enumset}(A_i) \cap \text{enumset}(A_j) \) implies \( i = j \) and \( \bigcup_{i=1}^{n} \text{enumset}(A_i) \subseteq \text{enumset}(A) \), or
\]

\[
(S_{[A_i]} \{ [A] \alpha \} \}
\]

The first tableau based decision procedure for CL is developed by Hansen [8]. Her formulation of modal saturations is simpler than ours because she instead chooses to have a separate property corresponding to superadditivity. However, such a property generates new conjunctions which are not subformulas of the original formula. In particular to our case where we also deal with concepts, this would require us to define a conjunction operator over \( \bigvee \theta \) and \( s : \bigvee C \) which we wished to avoid.

We are now in a position to define a Hintikka structure which is essentially equivalent to a CLALCO-model as far as the satisfiability of a CLALCO-formula is concerned.

Definition 3.4 Let \( H = \langle \Sigma, \Lambda, S, L, E, J \rangle \) be a basic Hintikka structure for \( \varphi \). \( H \) is said to be a Hintikka structure for \( \varphi \) if and only if:

\[
(P_{CD}) \ S(w) = S(v), \text{ for all } w, v \in \Sigma;
\]

\[
(P_{\Psi}) \text{ for all } w \in \Sigma, \text{ if } \{ \bigvee_1 \alpha_1, \ldots, \bigvee_n \alpha_n \} \text{ is a modal saturation in } w \text{ then there is some } v \in \Sigma \text{ such that } \alpha_1, \ldots, \alpha_n \in \Phi_v.
\]

Lemma 3.5 A CLALCO-formula \( \varphi \) is satisfiable iff there exists a Hintikka structure for \( \varphi \).

Representing individuals explicitly in tableau algorithms for expressive fragments of first-order modal logics with constant domains is problematic as far as termination is concerned. This observation is first made for modal description logics by Baader and Laux [3]. Later, quasimodels are proposed to show the decidability of various modal description logics [18]. Only after then it was possible to devise tableau based decision procedures for these logics [13,12] because the algorithms relied on the finite representation of individuals as offered by quasimodels. To this end, an individual (type) is defined as a function over the set of states.

Definition 3.6 Let \( H = \langle \Sigma, \Lambda, S, L, E, J \rangle \) be a basic Hintikka structure. A run \( r \) in \( H \) is a function associating with every \( w \in \Sigma \) a concept type \( r(w) \) in \( S(w) \).

A run \( r \) is defined over all states so that an individual (in the classical sense) corresponding to \( r \) is represented by some type in every state. This validates the constant domain assumption. However, one needs to impose several properties on runs in order for them to preserve satisfiability.

Definition 3.7 Let \( H = \langle \Sigma, \Lambda, S, L, E, J \rangle \) be a basic Hintikka structure for \( \varphi \). A Hintikka quasistructure for \( \varphi \) is a tuple \( Q = (H, R) \), where \( R \) is a set of runs in \( H \). Furthermore, it holds that:

\[ \text{types in the context of our Hintikka structures} \]
(P^i_r) for every i in N, the run r_i defined by r_i(w) = J_w(i), for all w ∈ Σ, is in R;
(P^s) for every w ∈ Σ and every s in S(w) such that s /∈ codom(J_w), there exists a run r in R such that r(w) = s;
(P^Q_S) for every w ∈ Σ and every r ∈ R, if Ψ is a modal saturation in w then there is some v in Σ such that r(w) : ∇C ∈ Ψ implies r(v) : C ∈ Φ_v and ∇v ∈ Ψ implies v ∈ Φ_v.

**Lemma 3.8** Let ϕ be a CL_{ALCO}-formula. There exists a Hintikka quasistructure for ϕ iff there exists a Hintikka structure for ϕ.

A more compact representation of a Hintikka quasistructure is possible by relaxing the definition of a run so that it can associate more than a single type for a state. However, we won’t define these ‘overloaded’ runs but dissolve their effect into a global property in the resulting structures.

**Definition 3.9** A basic Hintikka structure ⟨Σ, Λ, S, L, E, J⟩ for ϕ is a compact Hintikka quasistructure for ϕ if and only if for every w ∈ Σ,

(P^Q_S) if Ψ is a modal saturation in w then there is some v in Σ such that

- for every i in N, J_w(i) : ∇C ∈ Ψ implies J_v(i) : C ∈ Φ_v;
- s : ∇C ∈ Ψ and s /∈ codom(J_w) implies there exists a type t in S(v) such that \{C | s : ∇C ∈ Ψ\} ⊆ L_w(t);
- ∇v ∈ Ψ implies v ∈ Φ_v.

**Example 3.10** Consider the compact Hintikka quasistructure H = ⟨Σ, Λ, S, L, E, J⟩ for ϕ with Σ = {w, v} and L_w(s) = \{[a|C, [b|D, [b, c|E]\}, L_v(s) = \{C, D\}, L_v(t) = \{C, E\} (it does not matter how ϕ actually looks like). H is not a Hintikka quasistructure for ϕ because there exists no run r in H with r(w) = s, and hence, (P^s) is violated. The proof is easy, if there were to be an r with r(w) = s, whatever choice we make for r(v), i.e., r(v) = s or r(v) = t, (P^Q_S) would be violated. However, it is possible to modify H and convert it into a Hintikka quasistructure by duplicating the state v with all the necessary mappings.

The proof of the following Lemma generalizes the observation we made in our example.

**Lemma 3.11** Let ϕ be a CL_{ALCO}-formula. There exists a compact Hintikka quasistructure for ϕ iff there exists a Hintikka quasistructure for ϕ.

**Theorem 3.12** A CL_{ALCO} formula ϕ is satisfiable iff there exists a compact Hintikka quasistructure for ϕ.

**Proof.** Follows immediately from Lemmas 3.5, 3.8, and 3.11.

4 Tableau Algorithm for CL_{ALCO}

From Theorem 3.12, an algorithm which constructs a (finite) representation of a compact Hintikka quasistructure for a CL_{ALCO}-formula can be used as a decision procedure for the satisfiability of CL_{ALCO}-formulas. In this section, we describe such an algorithm, and we prove its termination, soundness, and completeness.
4.1 Definition of the Algorithm

Let $N_V$ be a set of countably infinite variables, and $<$ be the well-order relation on $N_V$. A term is either a variable or an individual name. Let $\varphi$ be a $\mathbf{CL}_{ALCO}$ formula. A constraint for $\varphi$ is (i) a formula in $\mathsf{fc}(\varphi)$, (ii) an atom of the form $x : C$ where $x$ is a term and $C \in \mathsf{cl}(\varphi)$, or (iii) an atom of the form $(x, y) : R$ where $x, y$ are terms and $R \in \mathsf{rol}(\varphi)$. A constraint system $S$ for $\varphi$ is a finite, nonempty set of constraints for $\varphi$. A completion set $T$ for $\varphi$ is a set of constraint systems for $\varphi$.

In order to avoid superfluous definitions, we will abuse the $\alpha, \beta$ uniform notation that we defined in Definition 3.2 for Hintikka structures. To this end, $\alpha$ and $\beta$ are placeholders for constraints. $\nabla \alpha$ is either equal to some $\nabla \vartheta$ or $x : \nabla C$, where $\nabla \in \{[\alpha], \langle \alpha \rangle\}$ for some coalitional term $\alpha$ and $x$ is a term. If $\nabla \alpha = \nabla \vartheta$ then $\alpha = \vartheta$; and if $\nabla \alpha = x : \nabla C$ then $\alpha = x : C$. Constraints of type $\nabla \alpha$ are also called modal constraints. More precisely, $[\alpha]\alpha$ is referred to as a positive modal constraint and $\langle \alpha \rangle \alpha$ as a negative modal constraint. Furthermore, a negative modal constraint $\langle \alpha \rangle \alpha$ is called proper if $\mathsf{enumset}(\alpha) \neq N_A$.

A term $x$ is in $S$ if $S$ contains a mention of $x$. A variable $x$ is fresh for $S$ if $x$ is not in $S$ and $x > y$ for all variables $y$ in $S$. We denote by $S[x/i]$ the constraint system obtained from $S$ by substituting every occurrence of the variable $x$ with the individual name $i$. If $(x, y) : R \in S$ for some role name $R$ and terms $x, y$ then $y$ is called an $R$-successor of $x$ in $S$, or just a successor when $R$ is not important.

A variable $x$ is blocked in $S$ if there is some other variable $y$ such that $\{C \mid x : C \in S\} \subseteq \{D \mid y : D \in S\}$ and $y < x$. In this case, we say that $y$ blocks $x$ in $S$. $S$ (and therefore $T$ if $S \in T$) is said to contain a clash if

- $x : \bot \in S$ for some term $x$,
- $\{x : C, x : \neg C\} \subseteq S$ for some term $x$ and some concept name $C$,
- $i : \neg[i] \in S$ for some individual name $i$, or
- $i : \{j\} \in S$ for individual names $i, j$.

The local expansion rules are given in Figure 1. The definition of the global expansion rule which adds new constraint systems into the completion set is more involved. In what follows, we will introduce this rule. We say that a rule, regardless of its type, is applicable to a constraint system $S$ iff its condition is satisfied in $S$.

Let $S$ be a constraint system. The equivalence relation $\sim_S$ on the set of variables occurring in $S$ is defined by taking $x \sim_S y$ iff $\{C \mid x : C \in S\} = \{D \mid y : D \in S\}$. The equivalence class generated by $x$ is denoted by $[x]_S$. Finally, $\sim(S) = \{\min([x]_S) : C \mid x : C \in S\} \cup \{\vartheta \mid \vartheta \in S\}$.

If $S$ and $S'$ are constraint systems then $S'$ is called a variant of $S$, written $S \approx S'$, iff there is a bijective function $f$ from the variables in $S$ onto the variables in $S'$ such that $S'$ is obtained from $S$ by replacing each variable $x$ from $S$ with $f(x)$.

Analogous to the modal saturations defined in Definition 3.3 for Hintikka structures, a subset $S'$ of a constraint system $S$ is called a modal saturation in $S$ if and only if $S'$ is equal to

(i) $\{[A_1]x_1, \ldots, [A_n]x_n\}$ such that $a \in \mathsf{enumset}(A_i) \cap \mathsf{enumset}(A_j)$ implies $i = j$,

(ii) $\{\langle \alpha \rangle \alpha, [A_1]x_1, \ldots, [A_n]x_n\}$ such that $a \in \mathsf{enumset}(A_i) \cap \mathsf{enumset}(A_j)$ implies $i = j$ and $\bigcup_{i=1}^{n} \mathsf{enumset}(A_i) \subseteq \mathsf{enumset}(A)$, or
The $R_r$ rule
- **Condition:** $\vartheta_1 \land \vartheta_2 \in S$ and $\{\vartheta_1, \vartheta_2\} \not\subseteq S$.
- **Action:** $S := S \cup \{\vartheta_1, \vartheta_2\}$.

The $R_v$ rule
- **Condition:** $\vartheta_1 \lor \vartheta_2 \in S$ and $\{\vartheta_1, \vartheta_2\} \cap S = \emptyset$.
- **Action:** $S := S \cup \{\psi\}$ for some $\psi \in \{\vartheta_1, \vartheta_2\}$.

The $R_1$ rule
- **Condition:** $x : C_1 \cap C_2 \in S$ and $\{x : C_1, x : C_2\} \not\subseteq S$.
- **Action:** $S := S \cup \{x : C_1, x : C_2\}$.

The $R_0$ rule
- **Condition:** $x : \exists R.C \in S$, $x$ is not blocked w.r.t. $S$, and $x$ has no $R$-successor $y$ in $S$ with $y : C \in S$.
- **Action:** $S := S \cup \{(x, y) : R.y : C\}$, where $y$ is fresh for $S$.

The $R_0$ rule
- **Condition:** $x : \forall R.C \in S$, there is a $R$-successor $y$ of $x$ in $S$ with $y : C \not\in S$.
- **Action:** $S := S \cup \{y : C\}$.

The $R_{l\geq}$ rule
- **Condition:** $\top \sqsubseteq C \in S$ and $x : C \not\in S$ for a term $x$ in $S$.
- **Action:** $S := S \cup \{x : C\}$.

The $R_{\leq}$ rule
- **Condition:** $\neg(\top \sqsubseteq C) \in S$ and there is no term $x$ such that $x : \neg C \in S$.
- **Action:** $S := S \cup \{x : \neg C\}$, where $x$ is fresh for $S$.

The $R_{\leq N_A}$ rule
- **Condition:** $\langle\text{enumterm}(N_A)\rangle \alpha \in S$ and $\{\alpha\} \not\subseteq S$.
- **Action:** $S := S \cup \{\alpha\}$.

Fig. 1. Local expansion rules for $\text{CL}_{\text{ALCO}}$.

(iii) $\{\langle A \rangle \alpha\}$,

such that none of the modal constraints mention a blocked variable.

The global expansion rule $R_{[\a]}$ is similar to the one in [6] and defined as follows.

**Condition:** $S$ is not marked as finished.

**Action:**

(i) Order linearly all positive and proper negative modal constraints in $S$ not mentioning blocked variables in such a way that all the positive modal constraints precede all the proper negative ones. Suppose the result is the following list:

$$L = [A_0]_{\alpha_0}, \ldots, [A_{m-1}]_{\alpha_{m-1}}, \langle A_0^0 \rangle_{\beta_0}, \ldots, \langle A_{n-1}^0 \rangle_{\beta_{n-1}}.$$  

Let $|L|$ be the length of $L$, i.e., $m+n$. Denote by $\Theta(S)$ the set $\{0, \ldots, |L|\}^{\sharp N_A}$.

As in the relational model, we identify the components of a tuple $\tau$ in $\Theta(S)$ by names, more precisely agent names, so that $\tau_{a}$ corresponds to the component of $\tau$ identified by $a$. Lastly, for every $\tau \in \Theta(S)$, denote by $\text{pos}(\tau)$ the set $\{a \mid \tau_{a} \geq m\}$; and by $\text{neg}(\tau)$ the number $\left\lceil \sum_{a \in \text{pos}(\tau)} (\tau_{a} - m) \right\rceil \bmod n$.

(ii) $\text{res} := \{\}$, where $\text{res}$ is a set of constraint systems.

(iii) Consider the elements of $\Theta(S)$ in the lexicographic order and for each $\tau \in \Theta(S)$ do the following:
(a) Create a constraint system

\[ S_τ = \{ α_i \ | \ [A_i]α_i ∈ S \ and \ ∀α ∈ enumset(A_i). τ_α = i \} \}

\{ β_j \ | \ [A_j]β_j ∈ S, neg(τ) = j, and N_A \ \text{enumset}(A_j) \subseteq \text{pos}(τ) \}.

(b) If \( S_τ = ∅ \) then continue with the next iteration.

(c) \( S_τ := ¬(S_τ ∪ \{ a : \{ a \} \ | \ a ∈ N_I \} \cup \{ x : τ \}) \}, \) where \( x \) is fresh for \( S \).

(d) If \( S_τ ≠ S_τ' \), for all \( S_τ' ∈ res \), then \( res := res ∪ \{ S_τ \} \).

(iv) \( T := T ∪ \{ res \} \).

(v) Mark \( S \) as finished.

Let \( ϕ \) be the \text{CLACCO} formula to be tested for satisfiability. The tableau algorithm starts with the initial completion set \( T = \{ S_0 \} \) for \( ϕ \), where \( S_0 = \{ ϕ \} ∪ \{ i : [i] \ | \ i ∈ N_I \} \cup \{ x_0 : τ \} \), \( x_0 \) being the first variable from \( N_I \). \( T \) is then expanded by repeatedly applying the rules in such a way that the global expansion rule is applied only when none of the local expansion rules is applicable, and among local expansion rules \( R_3 \) or \( R_5 \) is applicable only when none of the other local expansion rules is applicable to a constraint system. The expansion continues until the resulting completion set contains a clash or none of the rules is applicable to it. Such a completion set is called \text{complete}. If the expansion rules can be applied to \( T \) in such a way that they yield a complete and clash-free completion set then the algorithm returns “\( ϕ \) is satisfiable”, and “\( ϕ \) is unsatisfiable” otherwise. Note that the tableau algorithm is a \text{non-deterministic algorithm} due to \( R_\forall \) and \( R_\exists \). Each of these rules chooses which disjunct to add for a disjunctive formula (concept).

### 4.2 Correctness and Termination

**Theorem 4.1 (Termination)** Let \( n = \sharp \text{ccl}(ϕ) + \sharp \text{fcl}(ϕ) + \sharp N_I \), where \( \sharp \) denotes set cardinality. When started with the initial completion set \( T \) for \( ϕ \), the tableau algorithm terminates after the number of steps exponential in \( n \).

**Proof.** We first show that a local expansion rule can be applied at most once to the same constraint. If we didn’t have the rule \( R_1 \), this is obvious to see. In the presence of \( R_1 \), if \( R_3 \) is applied to some \( x : [i] \in S \) then \( \{ i : C | x : C ∈ S \} \cup \{ (y,i) : R | (y,x) : R ∈ S \} \⊆ S[x/i] \). For a term \( y \) of which \( x \) is a \( R \)-successor, this ensures that neither \( R_3 \) nor \( R_5 \) will be applied again to some \( y : ∃R.C ∈ S \) or \( y : ∀R.C ∈ S \), respectively. If \( x : ¬C ∈ S \) and \( τ \not\subseteq C ∈ S \) then \( i : ¬C ∈ S[x/i] \) ensures that \( R_5 \) will not be applied to \( τ \not\subseteq C ∈ S \). For all the other local expansion rules, the same holds trivially.

There can be at most \( \sharp \text{ccl}(ϕ) \) unblocked variables in \( S \) by the definition of blocking. New variables can only be introduced to \( S \) by \( R_3 \) or \( R_5 \). Call these rules generating and all the other local expansion rules non-generating. If \( R_3 \) has been applied to a constraint \( x : ∃R.C \) or \( x : ¬C \) has been added to \( S \) by \( R_5 \) then \( x \) will never be blocked in \( S \) because by the strategy of rule applications \( S \) was closed under the application of non-generating rules. Therefore, if a variable \( x \) is blocked then it is introduced by \( R_3 \), \( x \) is the successor of some unblocked term \( y \), and there is no successor of \( x \). As a consequence, the number of blocked variables in \( S \) can

\[ ^5 \text{Notice that by the strategy of rule applications, x can never have a successor before R_1 is applied} \]
Corollary 4.2 The tableau algorithm runs in NEXPTIME.
Remark 4.3 Pauly obtains the PSPACE lower bound of the satisfiability problem of CL by a polynomial reduction from the satisfiability problem of KD (the normal modal logic over serial frames) [15]. The formula satisfiability problem of $\text{KD}_{\text{ACC}}$ is NEXPTIME-hard [5]. Therefore, we conjecture that the NEXPTIME-hardness of $\text{CL}_{\text{ACC}}$ [17] (which is subsumed by $\text{CL}_{\text{ACCO}}$) could be shown by a similar reduction.

The following Lemma will be useful for establishing the soundness and completeness of the tableau algorithm. It says that $R_{\langle \alpha \rangle}$ finds all and only modal saturations in the constraint system to which it is applied.

Lemma 4.4 Suppose $S$ is a constraint system and that $R_{\langle \alpha \rangle}$ has been applied to $S$. A subset $\nabla S'$ of $S$ is a modal saturation in $S$ if and only if there is some $\tau \in \Theta(S)$ such that $S_\tau = S' \neq \emptyset$.

Proof. Denote by $\nabla S$ a constraint system containing only modal constraints and let $S = \{\alpha \mid \nabla \alpha \in \nabla S\}$. It is enough to consider subsets of $S$ containing only modal constraints because those are the ones actually by $R_{\langle \alpha \rangle}$. Thus, we look at all possible combinations of modal constraints.

1. Suppose $\nabla S'$ be a subset of $S$ that consists only of positive modal constraints and let $\text{ind}(\nabla S')$ be the set of all indices $i$ such that an element of $\nabla S'$ has the position $i$ in $\nabla$. Suppose $\nabla S'$ is a modal saturation in $S$. Then for all $i, k, \in \text{ind}(\nabla S')$, $\alpha \in \text{enumset}(\alpha_i) \cap \text{enumset}(\alpha_k)$ implies $i = k$. For every $i \in \text{ind}(\nabla S')$ and every $\alpha \in \text{enumset}(\alpha_i)$, set $\tau_\alpha = i$ and for every $\alpha \in N_A \setminus \bigcup_{i \in \text{ind}(S')} \text{enumset}(\alpha_i)$, set $\tau_\alpha = \text{min}(\text{ind}(\nabla S'))$. By the definition of $\Theta(S)$, $\tau$ is in $\Theta(S)$; and $S_\tau = S'$. Now suppose $\nabla S'$ is not a modal saturation in $S$. Then for some $i, k, \in \text{ind}(\nabla S')$, there is an $\alpha \in \text{enumset}(\alpha_i) \cap \text{enumset}(\alpha_k)$. This means that there were to be a $\tau \in \Theta(S)$ such that $S_\tau = S'$ then $\tau_\alpha = i$ and $\tau_\alpha = k$. But this is not possible.

2. Let $\nabla S' = \{\langle \alpha \rangle \alpha\}$. Any such $\nabla S'$ is a modal saturation in $S$; therefore, it is enough to show that there is some $\tau \in \Theta(S)$ such that $S_\tau = S' \neq \emptyset$. We consider two cases.

- Case $\text{enumset}(\alpha) \neq N_A$: Let $k$ be the position of $\langle \alpha \rangle \alpha$ in $\nabla$. By definition, $k \geq m$ and by assumption, there exists $\alpha' \in N_A \setminus \text{enumset}(\alpha)$. Set $\tau_\alpha' = k$ and $\tau_\alpha = m$ for every $\alpha \in N_A \setminus \{\alpha'\}$. As a consequence, $\text{neg}(\tau) = k - m$ and $N_A \setminus \text{enumset}(\alpha) \subseteq \text{pos}(\tau)$ which means that $\{\alpha\} = S_\tau$.

- Case $\text{enumset}(\alpha) = N_A$: By $R_{\langle \alpha \rangle}$, $\lceil \alpha \rceil$ is in $S$ and moreover it is a modal saturation in $S$. But by Case 1, we know that there is some $\tau \in \Theta(S)$ such that $S_\tau = \{\alpha\}$.

3. Let $\nabla S'$ be a subset of $S$ that contains more than one negative modal constraint. $\nabla S'$ is not a modal saturation in $S$ and there is no $\tau \in \Theta(S)$ such that $S_\tau = S'$ because $\text{neg}(\tau)$ allows us to choose at most one negative modal constraint.

4. Let $\nabla S'$ be a subset of $S$ containing some positive modal constraints and one negative modal constraint. The proof is a combination of the proofs for Cases 1 and 2. □

Corollary 4.5 Suppose $T$ is a completion set with $S \in T$ and that $R_{\langle \alpha \rangle}$ has been applied to $S$. If $S'$ is a modal saturation in $S$ then there is some $S''$ in $T$ such that

- for every $i \in N_I$, $i : \nabla C \in S'$ implies $i : C \in S''$;

15
for a variable $x$, $x : \forall C \in S'$ implies there exists a variable $y$ in $S''$ such that 
\{C \mid x : \forall C \in S'\} \subseteq \{D \mid y : D \in S''\};$

$\forall \vartheta \in S'$ implies $\vartheta \in S''$.

The proofs of following theorems are extensions of the respective ones in [17].

**Theorem 4.6 (Soundness)** If the tableau algorithm returns “$\varphi$ is satisfiable” for a $\text{CL}_\text{ALCO}$-formula $\varphi$ then $\varphi$ is satisfiable.

**Theorem 4.7 (Completeness)** If a $\text{CL}_\text{ALCO}$-formula $\varphi$ is satisfiable then the tableau algorithm returns “$\varphi$ is satisfiable”.

## 5 Conclusions

In this paper, we extend Coalition Description Logic [17] with nominals for individuals, and we use these nominals to refer to coalitions. This might be considered as a relatively simple extension of CDL, but it is well-balanced between expressivity and difficulty of reasoning. Regarding expressive power, one can reason about agents’ ability to influence themselves and to the best of our knowledge this is the first such coalition logic. As for the difficulty of reasoning, we use only basic set operations to reason in the modal component of the logic. Allowing more concept constructors to define coalitions would require model-checking techniques from the DL component; it looks like an interesting research direction for the future.

This study offers also an interesting reflection on the methodological level. In our previous work [17], we proposed a general framework for combining strategic and descriptive elements of a multi-agent system. However, it turned out that a nontrivial semantic machinery does not guarantee exciting specifications. Here, we present a small extension of the framework (one may be even tempted to call it slight) that allows to specify surprisingly sophisticated properties, as we hope to have demonstrated in Section 2.4. This shows that the practical usability of a language may very much depend on elements which seem minor from the theoretical point of view.
